

## In-class Lecture 4 - Scaling, Part 2

Tuesday, January 25, 2022 12:43 PM

## Mass-specific metabolic rates

## Estimate *E. coli* metabolic rate

Note to class: I decided to consider only the energy to assemble proteins

$$\frac{\text{energy consumed by } E. \text{coli to make another cell}}{\text{cell cycle time}} = \frac{\text{energy associated w/ putting together the proteins}}{\text{cell cycle time}}$$

We know that I pay  $+ATP_{\text{S}}$  /  $\alpha$ -assembled:

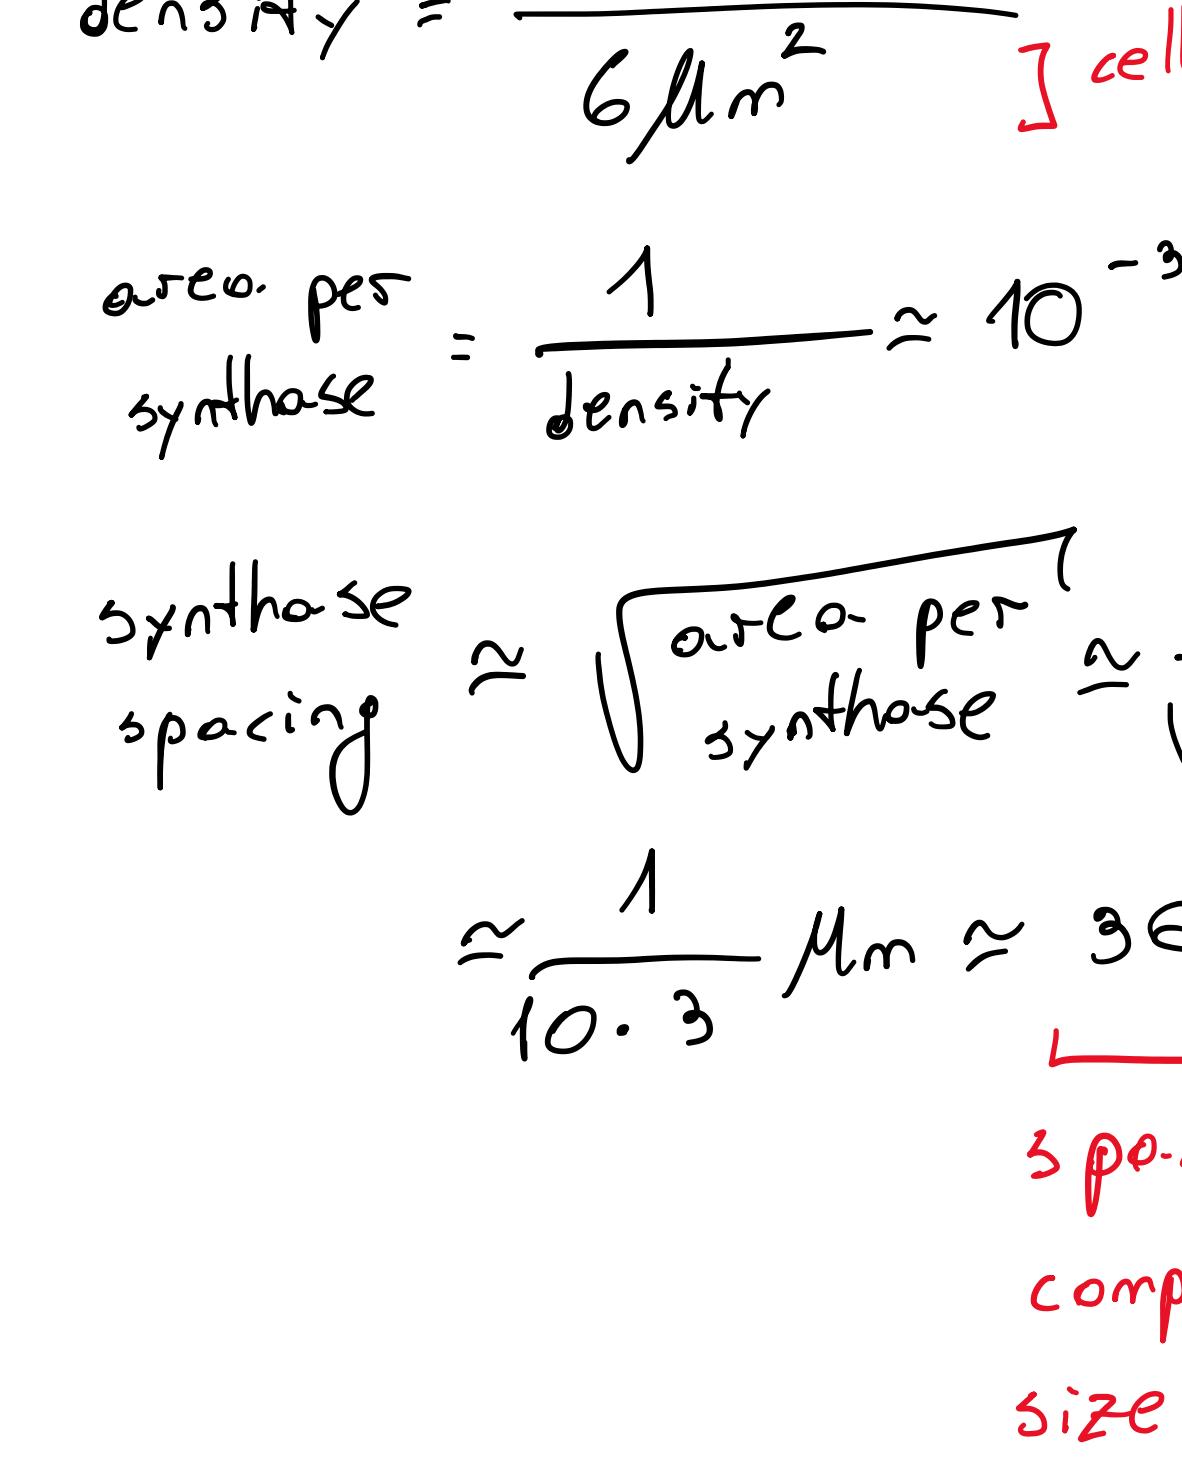

Table 3. ATP requirement for the formation of microbial cells from preformed monomers (glucose, amino acids and nucleic acid bases). Formation of lipids from acetate or glucose are separately considered.

| Macromolecule                             | Amount of monomer moles $\times 10^{-3}/\text{g cells}$ | ATP required per mole/monomer |         |                                       |
|---|---|-------------------------------|---------|---------------------------------------|
|   |   | Acetate                       | Glucose | moles $\times 10^{-3}/\text{g cells}$ |
| Polysaccharide                            | 10.26   | 2                             | 2       | 20.52                                 |
| Protein                                   | 47.85   | 4                             | 4       | 191.40                                |
| Lipid                                     | 1.40  | 33                            | 1       | 46.20                                 |
| RNA <sup>a</sup>                          | 4.60  | 5                             | 5       | 23.00                                 |
| DNA                                       | 0.96  | 6                             | 6       | 5.76                                  |
| Total                                     |   |                               |         | 255.98                                |
| ATP required for transport of Amino acids |   |                               | 47.85   | 47.85                                 |
| Acetate                                   |   |                               | 22.40   | —                                     |
| Potassium ions                            |   |                               | 1.92    | 1.92                                  |
| Phosphate                                 |   |                               | 7.74    | 7.74                                  |
| Total ATP requirement                     | 10000   |                               | 380.69  | 313.49                                |
| Y <sub>ATP</sub> = Total ATP requirement  |   | 26.4                          | 31.9    |                                       |

<sup>a</sup> For the RNA content the UMP content (Table 1) has been taken as basis.

$$\text{energy to pay the workers} = 3 \cdot 10^6 \text{ prots.}$$

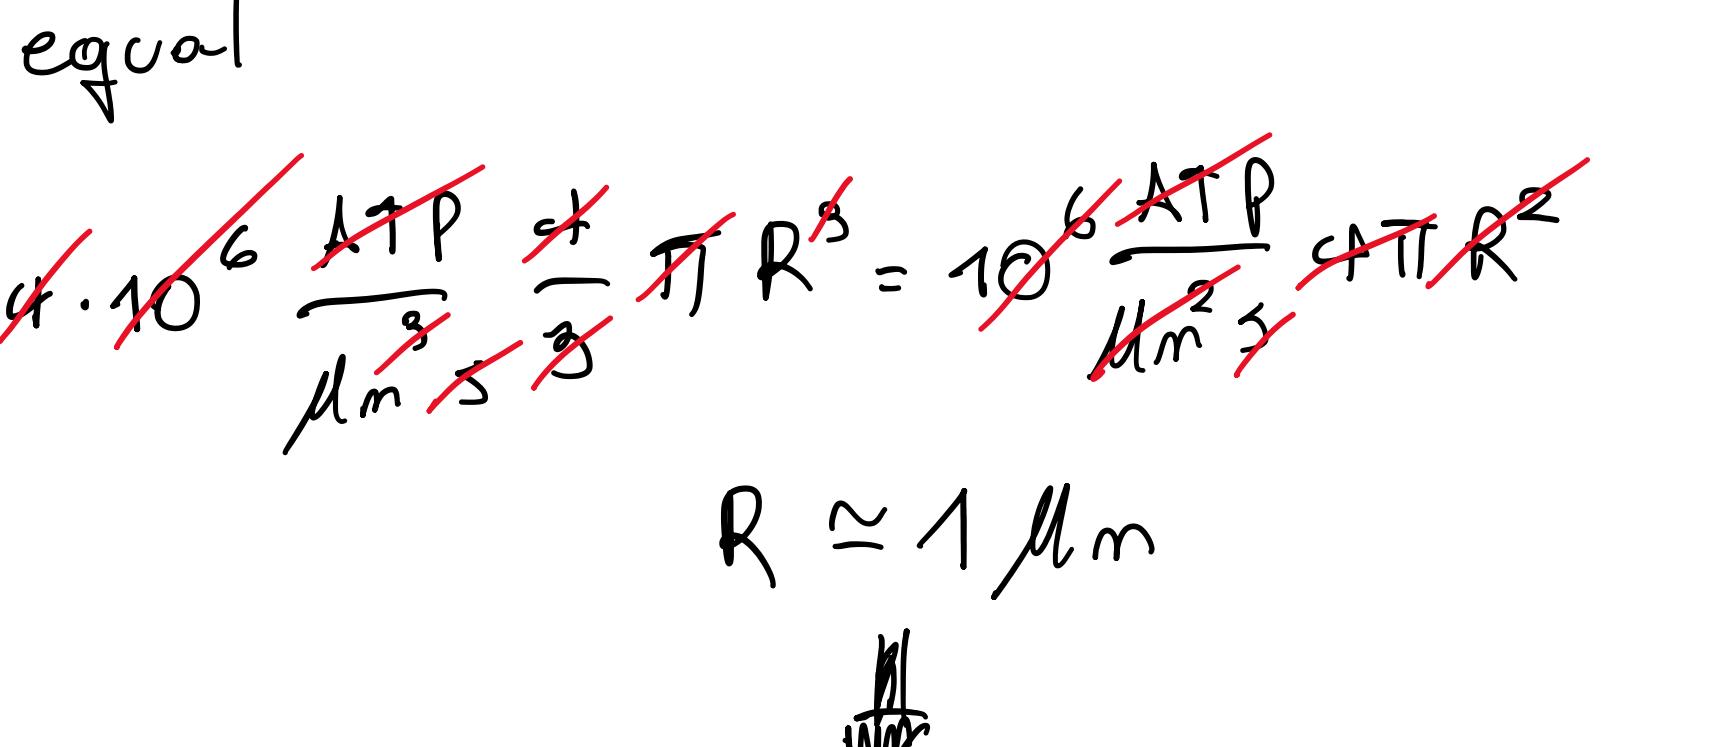

$$\cdot 300 \frac{\text{aa}}{\text{prot}} \cdot 4 \frac{\text{ATP}}{\text{aa}}$$

$$= 9 \cdot 10^8 \cdot 4 \text{ ATP}$$

$$= 4 \cdot 10^9 \text{ ATP}$$

Volumetric-specific energy required

$$M_V = \frac{4 \cdot 10^9 \text{ ATP}}{1 \mu\text{m}^3} \quad \text{we are in the right range!}$$

We see that there's a good agreement between our estimated metabolic rate for growth and that from Lynch + Marinov.

To calculate a rate, divide by the cell cycle

$$\text{Metabolic rate} = \frac{4 \cdot 10^9 \text{ ATP}}{1 \mu\text{m}^3 \cdot 1000 \text{ s}} \quad \text{~20 min}$$

$$= 4 \cdot 10^6 \frac{\text{ATP}}{\mu\text{m}^3 \cdot \text{s}}$$

How do you make all this ATP?

$\Rightarrow$  ATP synthase: spins  $\approx 100 \frac{\text{revolutions}}{\text{s}}$

$$= 100 \text{ Hz} \quad \text{comparable to jet engine!}$$

$$= 6000 \frac{\text{revol}}{\text{min}} \quad \text{cell area.}$$

$$= 6000 \text{ RPM} \quad \text{spacing is comparable to size! They're closely packed}$$

$$\text{synthase spacing} \approx \sqrt{\frac{\text{area per synthase}}{\text{area per cell}}} \approx \frac{1}{\sqrt{100 \cdot 100}} \mu\text{m}$$

$$\approx \frac{1}{10 \cdot 3} \mu\text{m} \approx 30 \text{ nm}$$

$$\text{synthase density} = \frac{5 \cdot 10^3 \text{ synthases}}{6 \mu\text{m}^2} \quad \text{from mass spec}$$

$$\text{area per synthase} = \frac{1}{\text{density}} \approx 10^{-3} \mu\text{m}^2$$

$$\text{synthase spacing} \approx \sqrt{\frac{\text{area per synthase}}{\text{area per cell}}} \approx \frac{1}{\sqrt{100 \cdot 100}} \mu\text{m}$$

$$\approx \frac{1}{10 \cdot 3} \mu\text{m} \approx 30 \text{ nm}$$

$$\text{synthase density} = \frac{5 \cdot 10^3 \text{ synthases}}{6 \mu\text{m}^2} \quad \text{cell area.}$$
